Abstract

This note summarizes my contributions to the estimation of extreme level curves. This problem is equivalent to estimating quantiles when covariate information is available and when their order converges to one as the sample size increases. Several estimators of these so-called ”extreme conditional quantiles” are developed and the links with boundary or frontier estimation are emphasized.

1 Extreme-value analysis

Extreme value theory is a branch of statistics dealing with the extreme deviations from the bulk of probability distributions. More specifically, it focuses on the limiting distributions for the minimum or the maximum of a large collection of random observations from the same arbitrary (unknown) distribution. Let \( x_1 < \cdots < x_n \) denote \( n \) ordered observations from a random variable \( X \) representing some quantity of interest. A \( p_n \)-quantile of \( X \) is the value \( q_{p_n} \) such that the probability that \( X \) is greater than \( q_{p_n} \) is \( p_n \), i.e. \( P(X > q_{p_n}) = p_n \). When \( p_n < 1/n \), such a quantile is said to be extreme since it is usually greater than the maximum observation \( x_n \). To estimate such extreme quantiles requires therefore specific methods to extrapolate information beyond the observed values of \( X \). Those methods are based on Extreme value theory. This kind of issues appeared in hydrology. One objective was to assess risk for highly unusual events, such as 100-year floods, starting from flows measured over 50 years.

The decay of the survival function \( P(X > x) = 1 - F(x) \), where \( F \) denotes the cumulative distribution function associated to \( X \), is driven by a real parameter called the extreme-value index \( \gamma \). When this parameter is positive, the survival function is said to be heavy-tailed, when this parameter is negative, the survival function vanishes above its right end point. If this parameter is zero, then the survival function decreases to zero at an exponential rate. An important part of our work is dedicated to the study of such distributions. For instance, in reliability, the distributions of interest are included in a semi-parametric family whose tails are decreasing exponentially fast.
These so-called Weibull tail-distributions encompass a variety of light-tailed distributions, such as Weibull, Gaussian, gamma and logistic distributions. Let us recall that a cumulative distribution function $F$ has a Weibull tail if it satisfies the following property: There exists $\theta > 0$ such that for all $\lambda > 0$,

$$
\lim_{y \to \infty} \frac{\log(1 - F(\lambda y))}{\log(1 - F(y))} = \lambda^{1/\theta}.
$$

I also addressed the estimation of extreme level curves. This problem is equivalent to estimating quantiles when covariate information is available and when their order converges to one as the sample size increases. We show that, under some conditions, these so-called "extreme conditional quantiles" can still be estimated through a kernel estimator of the conditional survival function. Sufficient conditions on the rate of convergence of their order to one are provided to obtain asymptotically Gaussian distributed estimators. Making use of this result, some estimators of the extreme-value parameters are introduced and extreme conditional quantiles estimators are deduced [1, 2, 3, 4, 5, 6, 7, 8, 9]. Finally, the tail copula is widely used to describe the dependence in the tail of multivariate distributions. In some situations such as risk management, the dependence structure may be linked with some covariate. The tail copula thus depends on this covariate and is referred to as the conditional tail copula. The aim of [10] is to propose a nonparametric estimator of the conditional tail copula and to establish its asymptotic normality.

Applications are found in hydrology [11, 12] and more generally in risk estimation [13, 14, 15].

2 Boundary or frontier estimation

In image analysis, the boundary estimation problem arises in image segmentation as well as in supervised learning. In the extreme quantiles approach, the boundary bounding the set of points is viewed as the larger level set of the points distribution. Its estimation is thus an extreme quantile curve estimation problem. Estimators based on projections [16, 17] as well as on kernel regression methods are applied on the extreme values set [18, 19]. These two families are unified in [20, 21] and the asymptotic distribution of the $L_1$ error is investigated in [22, 23, 24]. Applications to econometrics are considered in [25, 26].
